TRUST ARCHITECTURE

Secure by *absence.*

There is no server to breach. No platform to trust. No custodian between you and your data. Luna's security model doesn't protect your data from the world — it removes the world from the equation.

PLATFORM MODEL	SOVEREIGN MODEL
Trust the vendor	No vendor to trust

01 — ARCHITECTURE

Zero-custodian by design.

Every trust guarantee follows from one architectural decision: the AI lives as a file you own. No cloud. No account. No intermediary.

Zero Tenant

No server. No cloud instance. No VPC. Luna lives on your device as a SQLite file. There is no tenancy because there is no host.

→ Verify: open the .sqlite file yourself

Identity-Gated Access

FaceID recognition runs locally via FaceNet. No biometric data leaves the device. No admin can override. Your face is the only key.

→ Verify: enrollment and recognition are local-only processes

WORKSHOP STEWARDSHIP

Inspectable by Design

Every memory, every decision path, every relationship in the knowledge graph — readable in standard SQLite. No black boxes. No proprietary formats.

→ Verify: SELECT * FROM memory_nodes

Offline Sovereign

Full functionality without internet. Cloud is an optional guest, never the host. Network goes down, Luna doesn't. Power goes out, your data persists.

→ Verify: disconnect wifi and keep working

Zero Extraction

No telemetry. No usage analytics. No training data harvested. Nothing is sent, logged, or collected. The architecture doesn't permit it.

→ Verify: monitor network traffic — there is none

Survives the Vendor

If the project disappears tomorrow, your Luna file still works. No license server. No activation check. No sunset. The file is yours. Full stop.

→ Verify: all dependencies are permissive open-source

02 — COMPARISON

A different category.

Platform security asks "how do we protect what we hold?" Sovereign security asks "why are we holding it at all?"

CONCERN	PLATFORM MODEL	LUNA
Data residency	Vendor's cloud / your VPC	Your device. Period.
Access control	SSO via identity provider	Local FaceID — no server call
Encryption	Vendor encrypts at rest (AES 256)	You encrypt. You hold the key.
Audit trail	Vendor logs to their SIEM	Open the SQLite. Read it yourself.

CONCERN	PLATFORM MODEL	LUNA
Compliance	SOC 2, HIPAA, GDPR certification	No data leaves → nothing to regulate
Vendor failure	Data at risk / migration required	File still works. No dependency.
Training data	"We don't train on your data" (trust us)	Architecture makes extraction impossible

WORKSHOP STEWARDSHIP

03 — NON-NEGOTIABLES

Five commitments.

Not features. Not promises. Architectural constraints that cannot be violated without rebuilding the system from scratch.

◈

Sovereign

If it compromises local ownership, it's wrong

◉

Offline-First

Cloud is guest, never host

◎

Inspectable

No black boxes, ever

◇

Accessible

Must work in Kinoni, not just SF

◆

Respectful

Traditional knowledge stays with the community

04 — VERIFIABLE

Don't trust us. Check.

Every claim on this page is independently verifiable by the user. No audit firm required. No trust center to visit. The proof is in the file.

✓ **Open the database.** Luna's memory is a standard SQLite file. Any SQLite browser can read it. Every memory node, relationship, and decision path is queryable.

- **Monitor the network.** Run a packet sniffer while using Luna offline. Zero outbound connections. Zero telemetry. Zero phone-home.

- **Read the licenses.** Every dependency is permissive open-source (MIT, Apache 2.0, BSD). No proprietary lock-in. No commercial license risk.

- **Delete and recover.** Copy the file. Delete the original. Restore from your copy. Everything returns. No re-authentication. No cloud sync. The file is the source of truth.

- **Kill the internet.** Disconnect entirely. Luna still works. Every feature, every memory, every interaction — fully functional offline.

LUNA

Your AI is a file you own. Not a service you rent. Not a platform you depend on. A file. Sovereign, portable, yours.
